Board of Water Engineers
1410 Lavaca Street
Austin, Texas

Gentlemen:

Pursuant to the contract of August 28, 1958, we submit this summary report, together with all maps and supplementary data, complete as contemplated by the contract. This submission, therefore, constitutes the results of our investigation of the present availability of water from all Texas rivers and major streams under existing conditions of development and use.

Completing this study in only three months of contract time proved perhaps even more demanding - both for your staff and ours - than anyone anticipated. Cooperation simply is not an adequate word to describe the prompt, thoughtful and friendly assistance supplied without exception by the State and Federal agencies and by the several unnamed consulting engineers referred to in the report. While we can, and do, acknowledge our indebtedness for this assistance, we must also recognize the greater indebtedness of all the people of Texas. Such uniform willingness to facilitate the planning for which you are responsible manifestly reflects widespread belief in the urgent need for a soundly conceived Texas water plan.

Our work on this project has been under the full-time direction of Mr. C. R. Marks of our firm. He largely conceived the techniques used for processing and presenting the great mass of data; some of these are quite original, and may prove of substantial collateral value in future planning.

We trust that the information we have developed and assembled will adequately fulfill its intended purpose as a component part of the fundamental data needed for your forthcoming report to the Legislature of the State of Texas.

Respectfully submitted,

Lockwood, Andrews & Newnam

By: Mason G. Lockwood

SURFACE RUNOFF FROM TEXAS WATERSHEDS AND SUB-BASINS

SYNOPSIS

Presented herein is an inventory and analysis of data regarding drainage areas, surface runoff, consumptive uses, and reservoir storage for the State of Texas made to determine the present availability of surface water under existing conditions of water resources development and use.

One hundred thirty-eight watershed sub-basins comprising all of Texas and parts of adjoining states and Mexico were delineated and considered; 123 of these are in Texas. The total number includes 12 non-contributing areas in Texas and 5 in Mexico, for which no runoff was determined, so that runoff results are tabulated for only 121 sub-basins, 111 of which are in Texas.

The information developed by the analysis, as well as some of the data used which is not readily available, is listed in eight appendices, and is summarized in several tabulations in the text. The sub-basin drainage areas are shown on Map No. 1 and the estimated minimum and average annual sub-basin runoff is shown on Map No. 2.

The information made available by this study constitutes an essential first step in the development of a State water plan. By bringing together in one volume, runoff and water use data for the entire State, compiled on a uniform basis, this report also will be very helpful in preliminary studies of individual projects for the development and use of water.

INTRODUCTION

Purpose and Scope

The data contained in this report and shown on accompanying maps have been prepared to assist the Texas Board of Water Engineers in reporting on the present "availability" of surface water in Texas. "Availability" is here used in the sense of an inventory of water in the various watersheds and sub-basins within and bordering the State, all under existing conditions of water use and water resource development. Specifically, the term "availability of water" for any portion of a watershed, as used in this report, means the estimated amounts of water which, based upon past experience and upon existing reported consumptive uses in or above such portion of a watershed, can be considered for use in the planning of future watershed developments. No attempt has been made to evaluate possible increased uses upstream or present and potential uses downstream, under existing water rights and appropriations, as affecting the use of the data developed herein.

The specific objectives of the studies reported here were:

(1) To establish and delineate the principal sub-basins of each watershed within or bordering Texas, and to determine the area of each sub-basin.

(2) To determine the minimum and average net runoff from the uppermost and tributary sub-basins in each watershed; and, the same data on an incremental basis from each successive downstream sub-basin; all as if measured at the downstream end of the sub-basin; the determination to be based on the recorded or estimated streamflow experienced during the period 1940-1956, adjusted for present conditions of use, and for storage in reservoirs existing or under construction. The 1940-1956 period is considered the most representative one covered by adequate streamflow records.

(3) To show the results of these studies on two maps of the State, one delineating the sub-basins and giving their areas, and the other indicating the minimum and average runoff from each sub-basin.

In order to make the record more complete, the sub-basin areas shown and reported include out-of-state portions of watersheds entering Texas and of border streams. Estimated historic runoff values are also included for these sub-basins, except for those in Mexico, where large and growing uses and changes in storage make the historic runoff largely meaningless. Adjustments for the effects of these changes involve the International Water Compact, and are beyond the scope of this study. However, the results of studies by the International Boundary and Water Commission regarding the amount of water available to the United States at several points on the Rio Grande are included herein.

It should be noted that the data throughout the study are reported on a calendar year rather than a water year basis.

The application of a standardized method of analysis to all the sub-basins in the State is considered a means giving a reliable index of relative availability of water in these sub-basins, in the sense used here, and the results are applicable to preliminary planning studies. However, these results are not necessarily applicable in all cases to individual projects within an area without some modification, because the standardized approach may fail to reflect with complete accuracy all of the factors which may apply to such an individual project; some examples are discussed later.

The problem of analyzing the mass of data needed in determining minimum and average runoff for each sub-basin required, as a practical matter, electronic computer processing. A highly valuable by-product of this operation was a series of tabulations - one for each sub-basin analyzed by this means, listing the runoff for each month of the study period together with certain additional information. These data, together with the punched cards used in presenting the tabulations, will be extremely valuable in future water resource planning and development.

Appendices to this report contain the output data from the electronic computer operation as well as several sets of tabulations summarizing the data used in the studies and the results obtained.

Sources of Information

As much of the data and other information used in this study as possible was obtained from the Texas Board of Water Engineers. This information was supplemented by additional records of streamflow and reservoir contents obtained from the U. S. Geological Survey and the International Boundary and Water Commission, information secured from the U.S. Bureau of Reclamation and Corps of Engineers, precipitation records from the U.S. Weather Bureau and certain information obtained from several consulting engineers, either directly or from their published reports. Additional studies, analyses and limited field inspections have been made in cases where available data were not sufficient.

General Procedure

The procedure followed in this study was, first, analysis of the general character of runoff and water use in the several watersheds and, from this analysis, subdivision of these watersheds into appropriate sub-basins. After the selected subdivisions have been reviewed, modified somewhat, and approved by the Board of Water Engineers, these sub-basins were delineated on maps and the respective areas of each in square miles determined.

The next step was selection of the stream gages to be used in estimating the runoff from each sub-basin during the study period, 1940-56, and development of the necessary formulas to convert measured runoff at these gages to estimated runoff for the sub-basins. These formulas were applied in most cases through an electronic computer program, arranged to yield also printed tabulations of monthly runoff for each sub-basin and other useful data.

For sub-basins where streamflow data was lacking, it was necessary to estimate runoff as a proportion of the measured runoff in comparable sub-basins, in many cases with the aid of an additional factor based upon relative precipitation. Field inspection of the watershed and drainage pattern in one of the sub-basins was made to assist in runoff estimation.

Besides runoff determination for each sub-basin, it was necessary to collect the data on reported water uses in each sub-basin during the study period, and to develop a means for adjusting the historic streamflow records so that the sub-basin runoff to be reported would correspond to existing conditions of water diversion and use, rather than those which were obtained at the time of the measurements.

It was essential also to determine which reservoirs had been completed during the study period or are now under construction, and to obtain or make hypothetical operation studies for these reservoirs throughout the study period. The results of these operation studies were used to adjust further the measured runoff data, so that the final estimates of sub-basin runoff would uniformly reflect runoff to be expected under present conditions, as regulated by all existing reservoirs as well as those now actually under construction.

Unevaluated Factors

Because of the assigned scope of this study, certain factors which theoretically should enter into a fully refined and accurate study of this nature were not evaluated. Omission of these unevaluated factors generally will not materially affect the reliability of the results for use in overall development planning, or even in preliminary planning of specific projects.

There are, however, several areas in which the results indicate the need for collecting additional data to secure results refined enough for detailed planning studies.

The principal unevaluated factors are described in the following list:

(1) Available published information on watershed and sub-basin areas has been used without checking it against the latest topographic maps.

(2) Measured runoff has been converted to sub-basin runoff on the basis of drainage area ratios, without adjustment for variations in precipitation over the areas affected.

(3) Runoff has been adjusted to existing conditions of use only as reflected in the water use reports made to the Board of Water Engineers, with corrections only for large and obvious discrepancies, and without surveys to determine the possible unreported uses.

(4) Runoff has been adjusted to existing conditions of storage, including reservoirs under construction, by considering the effect of hypothetical operation of major reservoirs on an annual basis only. Inclusion of smaller reservoirs (under 10,000 acre feet, including farm tanks) and evaluation of all of these data on a monthly basis would change the results somewhat, especially the monthly runoffs from some specific sub-basins. This further refinement, however, certainly would not materially change the longtime averages, and it does not appear that it would affect the minimum annual runoff from any sub-basin more than the uncertainties regarding some of the other factors involved.

(5) Where runoff originating in an upper sub-basin passes through a downstream basin, the incremental runoff has been determined in all cases as the net addition to streamflow which occurs within the downstream basin, (or as the net subtraction if losses or diversions are greater than the inflow within the basin). These incremental inflows have not been compared with inflow from the downstream basin itself. If developments which would be affected by this factor were being planned, it would be necessary to make further studies to determine the runoff which would be available in downstream sub-basins with full use or material modification of the entering streamflow.

DELINEATION AND AREAS OF WATERSHEDS AND SUB-BASINS

Base Map Data

The base map of Texas used for showing the sub-basins and other data was obtained by starting with the 1:1,000,000 scale map of Texas published by the U. S. Geological Survey (completed in 1922, edition of 1948). The base map was obtained partially by tracing from a print of the original map and partially by photographic reproduction of major watersheds which had been traced from the same map by the Austin office of the U. S. Bureau of Reclamation in connection with the report, "Water Developments and Potentialities of the State of Texas".

To allow the maximum space for sub-basin data, the map shows only limited information, including the major rivers, certain towns and cities which are well distributed geographically, and the larger reservoirs which include conservation storage.

Establishment of Watershed Sub-Basins

The sub-basins selected for study are shown on the map and are further described in the tabulation in Appendix A. Each major tributary in each watershed was considered one sub-basin, or in some instances the tributary area was divided into two or more sub-basins, with additional sub-basins being selected along the main streams, generally separated at points where there are stream gages. The main stream sub-basins, and those which subdivide tributaries, were selected with reference to uniformity of climate conditions, location of major reservoirs, and areas of large diversions and use.

Determination of Watershed and Sub-Basin Boundaries

Main watershed boundaries were, for the most part, obtained by using the lines established by the U. S. Bureau of Reclamation, in the previously mentioned report. It is understood that the U.S.B.R. established these boundaries by reference to the latest available map data. The limits of non-contributing areas on the High Plains were also largely obtained by using the limits determined by the U.S.B.R. A few minor adjustments of boundaries determined by the U.S.B.R. were made where a check of the topographic maps indicated that it was necessary.

Boundaries of sub-basins in the entire western part of the State were determined by following divide lines as indicated by the 1:250,000 scale series of maps made by the Army Map Service and published by the U.S. Geological Survey. Near the Rio Grande, where certain quadrangles of this series are not yet complete, the dividing lines were obtained from the county highway maps of the Texas State Highway Department, many of which indicate topographic data in this area. In the eastern part of the State, except along the coast, dividing lines between sub-basins were obtained, for the most part, by following the divides between drainage patterns as shown on the 1:1,000,000 scale U.S.G.S. map previously described. Near the coast however, reference was made to the 1:250,000 series of maps and, in critical areas, to larger scale U.S.G.S. maps where available.

Determination of Sub-Basin and Watershed Areas

The most recent published data of the U.S.G.S. and I.B.W.C. where available, were used in the determination of areas. The areas of major watersheds within and outside of Texas were obtained from the unpublished records of the U.S.G.S.

Areas not available from the above sources were obtained by one of the following means:

(1) In the Canadian and Red watersheds, from the report entitled "Drainage Area Data, Arkansas White & Red River Basins" as compiled by the Corps of Engineers. This was supplemented, where necessary, by planimetering of certain Texas portions of watersheds common to two states.

(2) In the Sabine watersheds, from determinations made by the Corps of Engineers and obtained from their Fort Worth District Office, also supplemented by planimetering certain Texas portions of areas common to two states.

(3) Along the Gulf Coast, by planimetering the interior portions of sub-basins, broken down along county lines. These interior portions were added or subtracted from total county land areas, as determined by the U.S. Census Bureau and published in the Texas Almanac, to obtain the total land areas of coastal sub-basins. Thus the areas of these sub-basins include island as well as mainland areas.

(4) All needed areas along the Rio Grande were obtained from publications of the I.B.W.C., except those adjacent to the New Mexico border and the closed basins, all of which were planimetered, either on the 1:250,000 series of maps or on the county highway maps.

(5) Interior sub-basin areas, where not defined by published areas at gages, were generally obtained by using areas given by the Corps of Engineers in their various reports, with adjustments to make totals correspond to the U.S.G.S. areas at stream gages.

A process of estimation automatically gave watershed totals corresponding to those published or furnished by the U.S.G.S. and I.B.W.C., wherever such data are available. These total areas were summed up, along with areas of other sub-basins or portions thereof, coastal sub-basins, non-contributing areas, and portions of tributary areas which join the main streams outside the State. This total so obtained agreed with the total area of Texas published by the U.S. Census Bureau, with a discrepancy of less than 500 square miles out of the total 263,512 square miles. This discrepancy was adjusted by prorating it between areas 16 K and 15 Y.

Data for Individual Sub-Basins

All of the drainage areas for individual sub-basins, both within and adjoining Texas, are tabulated by watersheds in Appendix A. These tabulations also describe the sub-basin and list contributing and non-contributing areas. Portions of watersheds outside the state also are listed.

Tabular Summary and Data on Map No. 1

The individual areas listed in Appendix A are shown on their respective sub-basins on Map No. 1. Also, the watershed totals are tabulated on this map, and presented in the text as Table 1.

Suggested Additional Area Determinations

Although the area determinations made by the various agencies, supplemented by determinations made in this study as described above, are accurate enough for the purposes of this report, and check reasonably well with published area of the State, it would be desirable to refine these figures further whenever there is an opportunity. Some of the older determinations of the U.S.G.S. were necessarily made without benefit of very detailed topography.

As the State's topographic mapping program proceeds, it would be possible to refine portions of the area determinations as rapidly as the new maps are completed. Completion of the mapping program for the state, however, may require some time. Until this time, it appears that a careful, consistent and complete planimetering of all the watersheds, using the 1:250,000 series of Army Map Service maps, would yield results accurate enough for nearly any foreseeable purpose. A cooperative effort by the Board of Water Engineers and the various interested agencies might be the most feasible means of accomplishing this.

CONSUMPTIVE WATER USES

Sources of Data

Nearly all the data on consumptive water uses were obtained from the records of the Board of Water Engineers, which were furnished as total use above each gage, along with supplementary data for tributary sub-basins and breakdowns by types of use for specific sub-basins. The water service reports on which these tabulations were based are admittedly imperfect, especially in the earlier years; but are the best available without extremely detailed local surveys of old records and miscellaneous data.

Where the listed uses for certain years were markedly inconsistent with the general trend of use in a particular sub-basin, individual water service reports were examined. Where this indicated the strong possibility of an erroneous report

for such years, an appropriate adjustment was made in the use shown. These instances are noted in the watershed use tabulations, Appendix B.

In a few instances, reports of municipal uses and return flow obtained from the U.S.B.R. or the published records of the U.S.G.S. or from reports by consulting engineers, have been used to supplement or adjust the water uses as reported to the Board. These instances are also noted in the tabulations, Appendix B.

Types of Use Considered "Consumptive"

"Consumptive" uses in this study are considered to be those which divert the water from the stream, without an immediate return. Consumptive uses include municipal, industrial (other than cooling), irrigation and mining. Non-consumptive uses are those for hydro-electric power or for cooling purposes in steam or industrial plants.

Return flow allowance has been included in the estimates in only about half a dozen cases where it is known to be significant and where it can readily be determined or estimated. In other cases, the refinement possible by considering return flow does not appear to be consistent with the general accuracy of the records and the methods of estimation used.

Adjusting Historic Runoff for Present Conditions of Use

The minimum and average amounts of runoff available for consideration in future development and use in any sub-basin have been based upon the experienced historic runoff from that sub-basin as measured or estimated for the period 1940-1956 inclusive. The 17-year period 1940-1956 generally is a representative one, since it includes two or more years of very high runoff (in the 1940-1942 period) and several years of extreme drought (between 1950 and 1957). It is therefore assumed that the runoff experienced during the 1940-1956 period (referred to as the "study period") provides a reasonable and conservative estimate of the runoff that may be expected in the future.

If exactly the same rainfall pattern and other weather conditions which occurred in some past year should recur next year, the runoff from a sub-basin would not necessarily be the same as experienced in that past year. Changes in use, storage and land treatment measures, and other changes which have occurred since the year in question might change the measured runoff. For this study, only the effects of changes in use and major changes in storage conditions (the latter is discussed in the next section of this report) have been included in the analysis. The effects of other changes are relatively small, except in a few instances, and the data and analysis required to determine their effects are so extensive as to prohibit their inclusion.

For the purposes of this study, if the records show that there has been a substantial increase in use for any sub-basin during the study period, the measured runoff for any of the earlier years of the period has been adjusted by subtracting, from the measured runoff in that past year, the amount by which the present annual use exceeds the reported use in that year. Diversion from a stream of a given quantity at one point will not necessarily reduce all downstream flows by the same quantity. However, because of the effect of compensating return flow and channel losses, this method of adjustment is conservative in the sense that it yields runoff results which may be less than would actually occur, and it is considered sufficiently accurate for the purposes of this study. If this method results in too large an adjustment in some cases, this fact will offset, to some extent, other possible but unevaluated factors which may further reduce runoff if

the historic weather conditions which caused the runoff are repeated under present conditions of use.

Adjustments for changes in use have been made only in sub-basins where a definite and consistent trend of increasing use is evident. Where uses have been sporadic - higher in some years and lower in others - the historic runoff has not been adjusted. In the sub-basin tabulations, Appendix F, reported uses are listed in all cases. Where no use adjustment has been made, there is a note to that effect.

Basis for Determining "Present Conditions of Use"

The amounts of consumptive water use in each sub-basin, as reported to the Board of Water Engineers for the calendar year 1956, have generally been taken as the measure of existing, or present, conditions of water use. But in instances where it is known or believed that the use of water during 1956 is not representative of existing water demands, because of the lack of water or similar reasons; or where there is in progress a very large and predictable increase in the rate of water use in an area, other bases than the 1956 use have been adopted as a measure of "present conditions of use". These exceptions to the general rule are noted on the summaries of consumptive uses for the specific sub-basins involved (Appendix B).

Adjusting Monthly Runoff

In order to make the results of this study most useful in future planning work, the annual adjustments for changes in use have been applied to the monthly runoff values. The procedure followed was to subtract, from the runoff for each month of a particular year, 1/12 of the annual adjustment for that year with respect to uses for municipal, industrial or mining purposes; and, similarly to subtract a varying portion of the annual adjustment for irrigation purposes. The portion of the annual irrigation adjustment subtracted for each month of the calendar year was varied from one part of the State to the other, on the basis of experienced average irrigation water demand for each month for representative points in each area. (The factors for proportioning the annual use to each month of the year in a given area are designated as a "use code" as discussed below.)

This process admittedly is approximate, especially concerning municipal water use, but the approximations involved are probably of less consequence than the uncertainties regarding past records of water use and present water demands.

Adjustments for Changes in Return Flow

Where large and predictable quantities of return flow enter a sub-basin, and where substantial increases in such returns have occurred during the period studied, an allowance for return flow has been included in the use adjustment. Naturally the effect of an increase in return flow over the years is just the opposite of that of an increase in use.

Use Adjustment for Coastal Areas

For the coastal sub-basins and for some of those near the mouths of the main rivers, the historic runoff was estimated by a combination area and precipitation ratio from measured runoff on central areas which have little or no uses. These estimated amounts reflect no historic uses and therefore the use adjustment was assumed to be the full amount of the present use, rather than the increase in use as was assumed for sub-basins with measured historic flows.

Summary of Consumptive Uses

The data on consumptive uses tabulated by watersheds in Appendix B is summarized for the State in Table 2.

REGULATION OF RUNOFF BY STORAGE IN RESERVOIRS

Effects of Regulation on Historic Streamflows

To estimate the amount of surface water which will actually run off in the future from the various sub-basins and be available for development and use, it is necessary to use historic records of streamflow. It is also necessary, however, to consider the effects of all reservoirs which would change the amount of runoff should past weather cycles be repeated under present conditions of watershed development and use. In this study all major reservoirs now completed or actually under construction have been so considered.

The effect of reservoirs which were completed and filled before the beginning of the study period has generally been assumed to be the same as is reflected in the historic records, and the only adjustments made in such cases are those due to changes in water use. This procedure is not completely accurate, because changes in water use will change the operation of the reservoirs, but the effect of these changes in operation generally is of minor importance.

For reservoirs constructed during the study period, the same assumption has been made for the portion of the period after these reservoirs were completed and filled. For reservoirs completed after the beginning of the study period, and for those now under construction, hypothetical operating studies have been made to estimate the changes in historic streamflow which would have been caused by these reservoirs had they been completed and filled prior to the beginning of the study period.

Effect of Types of Reservoir Regulation

The effects of reservoir operation and use upon the streamflow downstream varies widely according to the purpose and use of the reservoir.

If water is being diverted from the reservoir for municipal, industrial or irrigation use, the reservoir may intercept a large part of the streamflow and hold it until it is used, evaporated or partially returned as water or sewage.

If the water is to be used for generating hydroelectric power or released for downstream diversion, the reservoir may operate merely to smooth out irregularities in the streamflow.

A reservoir designed solely for flood control generally is filled only during floods and emptied as soon thereafter as the safe rate of release will permit.

Despite these different types of regulation and their various effects on downstream flows, if the effects of changes in use and those caused by the reservoir itself are treated separately, as has been done in this study, the effect of the reservoir storage alone for any type of reservoir upon the unregulated streamflow during any period of time can be determined as the sum of two quantities, namely:

(1) The amount of water lost by evaporation.

(2) The change in contents of the reservoir.

TABLE 2

SUMMARY OF CONSUMPTIVE USES

WATERSHED	TOTAL CONSUMPTIVE USE IN WATERSHED, AC. FT. PER YEAR REPORTED* 1956	ADOPTED "PRESENT CONDITIONS"

GUADALUPE	46,925	103,592
SAN ANTONIO	10,786	10,786
NUECES	53,184	80,085
RIO GRANDE	1,193,440	1,971,535
R.G. DRAINAGE & COASTAL	133,508	165,148
TOTAL	3,411,661	4,756,005

NOTE: Amounts listed under Adopted, "Present Conditions", where different from those reported in 1956, indicate that 1956 use is not considered representative of present conditions.

* With adjustments as noted in text.

The natural streamflow will be reduced by the amount of water evaporated in the reservoir and also by the amount of water stored in the reservoir. If water is released from storage, the streamflow will be increased by the amount of the release.

Basis for Operation Studies

Where a reservoir is intended to supply water for diversion away from the stream, the actual or estimated amounts of diversion under present conditions of use, rather than the maximum yield of the reservoir, have formed the basis of the operation studies.

Where a reservoir is intended to regulate downstream flow, the full yield of the reservoir has been used as a basis for the operation studies.

The operation studies made for this report have been carried out on an annual basis only. This procedure may introduce a considerable inaccuracy in a particular year, and would not suffice to determine the safe yield of the reservoir. But since the only purpose of these operation studies was to determine the reservoir's effect on minimum and average annual runoff, the procedure used is considered sufficiently accurate. The scope of this study did not permit making operation studies on a monthly basis for all reservoirs involved.

Only those reservoirs having a storage capacity in excess of 10,000 acre-feet have been considered, since the aggregate effect of the smaller reservoirs would not be sufficient to warrant their inclusion.

Sources of Data

Inflow to a reservoir was generally obtained by applying a drainage area ratio to the runoff at the closest measuring point. Estimated inflow and net evaporation depth determined by others for the site in question were used where available, and in some cases use was made of available evaporation data for other reservoirs in the same vicinity or in similar climate zones. In only a few cases, where no evaporation data was available, were actual estimates of net evaporation depths made.

Area-capacity data were obtained, for the most part, from the files of the Board of Water Engineers, or from the agencies operating the reservoirs. In some cases these data were estimated from the published records of the U.S. Geological Survey; which source was also used for the capacities of all reservoirs.

The results of hypothetical operation studies made by the Corps of Engineers, the Bureau of Reclamation, the International Boundary and Water Commission, or consulting engineers were obtained and used where available and applicable. Where these did not cover the full period up to the time the reservoirs were filled, the studies made by others were extended.

Adjustments During Filling Period

During the initial filling period of any reservoir completed during the study period, the storage adjustment was estimated as the difference between the actual effect the reservoir had during its initial filling and the effect on streamflow the reservoir would have had if filled before the beginning of the study period and operated throughout this period.

Adjustments for Reservoirs in Border Streams

The only reservoirs on border streams are Lake Texoma on the Red River and Falcon Reservoir on the Rio Grande. The I.B.W.C. has estimated the effect under present conditions, with allowances for increase of use which can be expected in the immediate future, of the latter reservoir on water available to the United States. This estimate has been adopted. The effect of Lake Texoma on the runoff from Texas and Oklahoma respectively has been computed, for the purpose of this report, by assuming that 50% of the total storage adjustment in any year is applicable to each state. This proportion is the same as the proportion of the drainage areas in each state above the dam site.

Results of Reservoir Storage and Operation

The amount of conservation storage in the various major reservoirs in or bordering the states is summarized by watersheds in Appendix C and, for the state as a whole, in Table 3. The time of completion of the various storage increments also is shown, and the reservoirs included in this study are noted. The amounts of the total storage adjustment, which is the algebraic sum of evaporation plus change in contents, with reversed sign, is shown for each sub-basin in the tabulations of Appendix F.

PROCEDURE FOR DETERMINING RUNOFF FROM SUB-BASINS

Sources of Data

For about 80% of the sub-basins, the basic data for runoff were obtained by using punch-card records of streamflow obtained from the Board of Water Engineers, or from the published or advance records of the U.S.G.S. and the I.B.W.C. These records were sufficient to permit determination or estimation of the runoff during the study period for most of the sub-basins, with the addition of a small amount of estimated data to fill gaps in the records.

On the 10 contributing coastal sub-basins and on 9 of the sub-basins at the lower ends of the main river watersheds, there are no gaging stations to measure runoff. Runoff for these sub-basins was estimated, on an annual basis only, using measured runoff in control areas consisting of the closest comparable basins for which runoff has been measured. The runoff for the unmeasured coastal areas in any year was computed by applying to the runoff in the control area, first, the ratio of the area of the coastal basin to that of the control area, and, second, the ratio of the average precipitation on the coastal area for that year to the corresponding precipitation in the control area.

A similar process was applied, on a monthly basis, to the upper portion of the Prairie Dog Town Fork of the Red River for the years 1953 to 1957, for which virtually no runoff data is available on this river. (The control area in this case was the South Fork of the Red River above the gage near Carter.)

General Procedure

In only relatively few of the sub-basins were gages located, or gage readings made, throughout the study period, so that the runoff for the sub-basin was actually measured by a gage, or by the difference between the quantities measured at two successive gages on a stream. It was therefore necessary to estimate the

TABLE 3

SUMMARY OF RESERVOIR STORAGE

Conservation Storage in Reservoirs Over 10,000 Acre-Feet, Completed or Under Construction

TOTAL CONSERVATION STORAGE 10,773,322 Acre-Feet

runoff from the sub-basin by formulas for converting the measured runoff at the nearest available gage or gages to the runoff for the sub-basin.

Since most of the sub-basins are relatively small and extend over a rather limited climatic range, it was considered unnecessary for the formulas to allow for the effect of variation in precipitation over the watershed. Therefore, the formulas were based entirely on drainage area ratios. The runoff from an area larger than that measured by a gage, however, has not generally been determined simply as the measured flow multiplied by the ratios of the areas except in cases where this process is clearly the most applicable one. Instead, where possible, runoff measured at other gages on the river or its tributaries has been used, in order to limit the proportioning process as much as possible to a compact area which does not include the upper portions of any watershed. This process is illustrated by the diagram in Fig. 1 and explanation thereof.

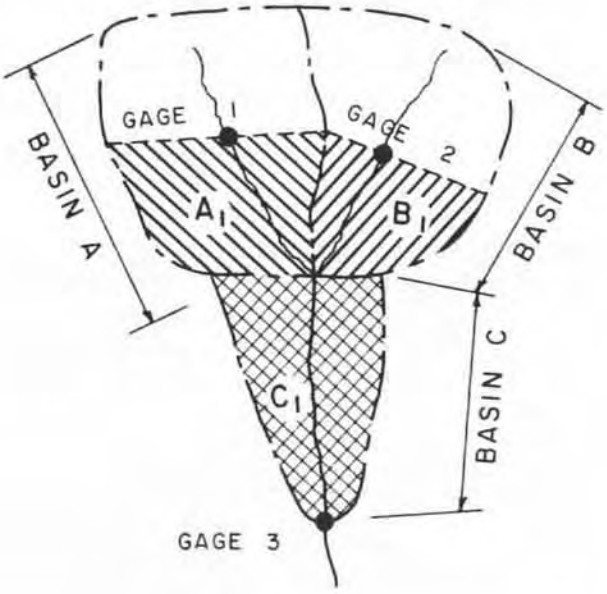

Fig. 1

Referring to **Fig. 1,** if Q_1, Q_2 and Q_3 are measured flows at the three gages: Q_a, Q_b and Q_c the computed flows at the lower edges of the three areas: A_1, B_1 and C_1 the areas between the gages; then,

$$Q_a = Q_1 + \frac{A_1}{A_1 + B_1 + C_1} \left[Q_3 - (Q_1 + Q_2)\right]$$

$$Q_b = Q_2 + \frac{B_1}{A_1 + B_1 + C_1} \left[Q_3 - (Q_1 + Q_2)\right]$$

$$Q_c = \frac{C_1}{A_1 + B_1 + C_1} \left[Q_3 - (Q_1 + Q_2)\right]$$

General Formula

The preceding formulas expand into the following general form, Q_x being the runoff from any sub-basin.

$$Q_x = K_1 Q_1 + K_2 Q_2 + K_3 Q_3 + \text{----------}$$

The number of terms depends upon the number of gages involved, and the coefficients K_1, K_2, and K_3 etc., which may be either positive or negative, are different for each sub-basin involving this particular combination of gages.

This formula can be further extended to include the adjustments for change in use.

Letting M_p = Present Municipal & Industrial Use

M_n = Municipal & Industrial Use in any year

A_p = Present Agricultural Use (irrigation)

A_n = Agricultural Use in any year

K_a = Monthly coefficient for agricultural use

then for the assumption already explained regarding adjustments for changes in use, the entire formula becomes:

$$Q_x = K_1 Q_1 + K_2 Q_2 + K_3 Q_3 + \text{----------} - \frac{M_p}{12} + \frac{M_n}{12} - K_a \times A_p + K_a \times A_n$$

A limitation was placed upon the application of this formula in all sub-basins so located that they do not receive runoff from another upstream sub-basin. This limitation was that, if the runoff resulting from application of the formula in any month were negative, the runoff for such a month would be reported as zero, since it obviously is impossible to have less than zero runoff originating in any sub-basin.

Tabulation of Gage Factors

Application of the general formula to the various sub-basins results in a series of "gage factors" for the various gages used in each sub-basin: these factors are the coefficients K_1, K_2 and K_3, etc. in the above equation.

The tabulation in Part I of Appendix D gives the identifying numbers, description, and period of record of all stream gages used in this analysis. The tabulations in Part II of Appendix D, one for each watershed, give the identifying numbers of the gages used in estimating the runoff for each sub-basin as well as the corresponding gage factors. The relative location of the gages used in the analysis, as well as other gages in each watershed, is shown in diagrammatic form on a series of charts in Appendix E. (This information for Watershed 1 is shown on the diagram for this watershed in the Appendix, H-1.) The tabulations in Part II of Appendix D also indicate, in the last two columns, the agricultural "Use Code" which applies to this particular sub-basin, and whether or not a storage adjustment is required. The use codes 0 and 00 are identical, in effect, but code 0 indicates no reported use and code 00 indicates that no use adjustment was made. The monthly factors making up the irrigation use codes and the portions of the state to which they apply are listed in Table 4.

Irrigation Use Codes

The irrigation use codes listed in Table 4 were derived as follows:

Code NW: This was determined from the average monthly use of water from the Altus Dam project in Oklahoma for the water years 1951 to 1956 inclusive as listed by the U.S.G.S. in the water supply papers.

APPLICATION OF CODES - GENERAL AREAS

NW - CANADIAN AND UPPER RED RIVER

NC - UPPER AND CENTRAL TRINITY, BRAZOS AND COLORADO

MC - GUADALUPE RIVER

SC - SAN ANTONIO AND NUECES RIVERS

CO - COASTAL (RICE IRRIGATION)

UR - UPPER RIO GRANDE AND PECOS RIVERS

MR - MIDDLE RIO GRANDE (NOT USED)

LR - LOWER RIO GRANDE

0 - NO USE

00 - NO USE ADJUSTMENT

Code NC: This was determined from the average monthly irrigation requirements for the Brownwood Project for the calendar years 1936 - 1956 inclusive, for 15,000 acres as given us by the Austin office of the U.S.B.R.

Code MC: This was determined as a sort of an average between the NC and the SC codes.

Code SC: This was determined from the average monthly diversions from the Medina River in the Medina Canal from 1923 - 1934 inclusive, as given in U.S.G.S. Water Supply Paper No. 850.

Code CO: This was determined as the approximate average pumpages for the American and Richmond Canal Companies for the years 1932 - 1954 inclusive.

Codes UR, MR & LR: These were determined from the long time averages published in the most recent IBWC bulletin for the American Canal, Maverick Canal and Lower Rio Grande diversions respectively.

The application of the use adjustment to the monthly flows for upper sub-basins, and to the annual flow for the coastal sub-basins and the lowermost sub-basins of the main rivers, is described on pages 8 through 10, and the "use codes" and their area of application are listed in Table 4. In addition, the use code actually applied to each sub-basin is given in the next to the last column of the tabulation of gage factors on Appendix D.

The amount of the use adjustments applied to any sub-basin can be determined from the tabulations on Appendix B. The use adjustment for any year is generally the difference between the "present use" and the reported use in any given year. In most cases this adjustment is broken down between municipal and industrial uses, and irrigation uses, since a different monthly adjustment factor is applied to each. It should be noted however, that where the use code 00 appears, no use adjustment to the historic flows was made, because there was no definite trend apparent as to increasing use. It should also be noted that negative use adjustments were not made, except for return flow in the instances noted.

Electronic Computer Operation

Calculations on the electronic digital computer were performed by Forney W. Fleming, Consulting Engineer, and John C. Allred, Ph. D., Consulting Physicist, using the IBM 650 Computer.

The primary purpose of the computer operation was the calculation, from runoff records, gage coefficients, annual consumptive uses, and storage adjustments, of the 17 year average annual and the minimum yearly runoff for each sub-basin under present conditions. It was easily possible, however, by using the intermediate results necessary to accomplish the basic calculations, to calculate the monthly and annual averages for three sub-periods, two of 6 years and one of 5 years. It was also possible to compute the minimum running totals for periods extending from one month to ten years. In addition, the computer operation permitted the printing in convenient tabular form of part of the input data and all of the output data. Accordingly, these data, including monthly values for runoff adjusted to present conditions of use, were tabulated for each of the 95 sub-basins in which the computer operation was utilized.

The data to be processed consisted of the annual uses (broken down where significant into irrigation and non-irrigation), the irrigation use code, the gage coefficients, the historic flows at the selected gages, and the storage adjustments.

A schematic box diagram (Figure 2) indicates the input data and the operations performed upon it.

Adjustments to the calculated flows were made by the addition, by algebraic means, of the difference between the amount of uses of either type in each year under consideration and the total use of the same type for 1956. In cases where some other use value than that of 1956 was adopted as a measure of "present use", the adopted amount was substituted as a fictitious 1956 use and the output sheet changed to report the actual 1956 use. In this way the 1956 runoff was not adjusted, since in most cases a low use in 1956 reflected a water shortage in that year. Inasmuch as the calculations for distributing annual uses on a monthly basis were most easily made by operations on the differential between the 1956 uses and those of the subject year, the data for them was an early item of input, with intermediate results stored internally until runoff data was processed.

In the next operation, the unadjusted monthly sub-basin runoff was calculated from the predetermined gage factors and the punched-card record of monthly flows at the selected gages. This completed monthly runoff was then adjusted for changes in consumptive use. The resulting adjusted monthly runoff values were totaled for annual values and storage adjustments applied to this latter figure.

Monthly and annual adjusted values were held in storage until the entire period under study had been calculated, and then all averages were computed through the addition of the pertinent quantities for a specified period and division of the sum by the length of the period.

Computations for the minimum running totals were calculated by first adding the initial series of values for the length of period under study. Thereafter a single following month was added to the total and a preceding month deducted, the resultant compared with the previous total, and the minimum figure, with ending month, retained. Successive repetition of this process produced the minimum month, the minimum 3 months, the minimum 6 months, the minimum one year, two year, five year and ten year totals, and the month terminating the period of minimum flow. The minimum calendar year runoff was not selected in the computer process since it could be very easily picked out by inspection and added to the output sheet.

In these calculations it is estimated that approximately 150,000 specific items of information were introduced into the computer. Since the transcription and computation of these data into a form suitable for manual operations would have been a herculean task, the necessity for the computer in this study is evident.

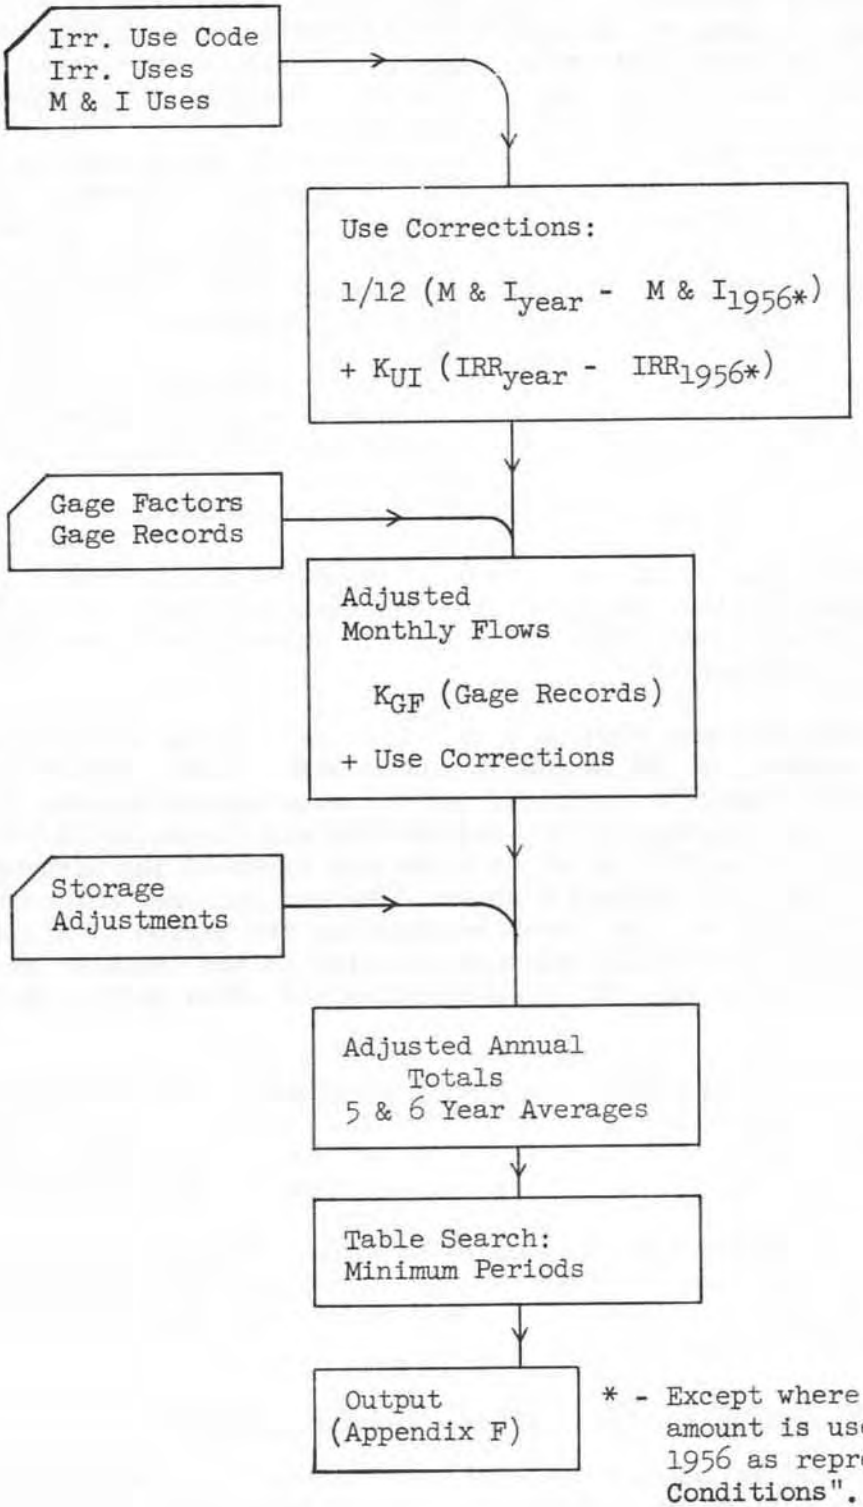
Upon completion of the calculations, output data was printed in the format shown in Appendix F with some necessary additions. These additions basically were the left-hand column of each table plus titles and qualitative and non-uniform notes relating to specific sub-basins.

Special Procedures Where Runoff Data are Lacking

The general procedure followed in coastal sub-basins, where no runoff measurments are available, has already been described. The locations of the coastal areas and their principal streams, the adjacent main river sub-basins, the "control" areas and the stream gages used with the record period of each one not shown on the gage charts, are all indicated on the final chart of Appendix E.

In sub-basin 16 J, studies made for another purpose were used to estimate the annual runoff, using rainfall vs. runoff curves, derived from an analysis on

SCHEMATIC DIAGRAM OF COMPUTER OPERATION



* - Except where a different amount is used in place of 1956 as representing "Present Conditions".

Fig. 2

the San Antonio River between the Falls City and Goliad gages, and the Mission River, to estimate runoff from the northern part of the area, and using several area precipitation stations to estimate the average sub-basin rainfall. A field inspection of the area, however, showed the southern half to have almost no drainage pattern, and that portion closer to the coast overlain by an ancient sand sheet. Based on these considerations, only one-fourth of the runoff obtained from the curves was estimated as obtainable from this part of the drainage area.

It appears certain there will be no runoff to the coast from Area 16 K, because of the sand dunes near the coast that absorb all the runoff except possibly a small amount during the most severe floods.

In several other sub-basins it was necessary to piece out records for a portion of a month. This was generally done by using a proportion of the closest known watershed. On the Upper Red River it was necessary to create synthetic runoff records in two instances, one on the Prairie Dog Town Fork, as already described, and one on the Salt Fork, for about a year after the Altus Reservoir was built upstream from the Magnum gage. In this case the records were adjusted for the estimated effect of the reservoir.

For sub-basin 13 A, the Medina River above Riomedina, there were long periods when no records were kept. In these cases there appeared to be no reliable way of estimating runoff, and the reported data was based upon the periods of actual record rather than on the study period used elsewhere. A monthly breakdown of the average annual runoff, however, was assumed for the purpose of estimating the runoff from the next downstream sub-basin.

For sub-basin 14 A, the West Nueces above Bracketville, there is also an extensive gap in the records. Since much of this runoff is absorbed in the Balcones Fault above the gage, there is no way of estimating runoff from rainfall. The estimated flow for the period of no record was therefore based upon a proportion of the flow on the Nueces River below Uvalde. This proportion assumed was based upon past records, spot flood measurements on the West Nueces, and runoff at other nearby gages. Both sub-basin 13 A and 14 A are reported on an annual basis.

The runoff for the Devil's River watershed was reported only on an annual basis, because recent measurements by the I.B.W.C. indicate that a spring flow of about 100,000 acre-feet per year enters the river in the 4.5 miles between the Del Rio gage and the mouth. The quantity of spring flow added to the flows at Del Rio in each year was proportioned to the non-flood flow at Del Rio on a basis estimated from the records for the past two and one-half years at a new station farther downstream.

RUNOFF RESULTS FOR SUB-BASINS

Tabulation of Computer and other Output Data

The output of the computer operation for all of the 95 sub-basins analyzed by this method is given in a series of tabulations in Appendix F. These tabulations, with their appended notes, are generally self-explanatory.

Interspersed in their proper order in Appendix F are tabulations on an annual rather than a monthly basis for the 25 sub-basins analyzed by manual computation, generally by using precipitation records as previously discussed. Included in this number are tabulations for sub-basins 13 A, 14 A and 15 F, where the runoff records are not adequate to provide reliable monthly runoff estimates, for the

reasons already discussed. Also included are tabulations for sub-basins 10 A and 10 C, where special conditions of storage and use made the general formula inapplicable, so that computer operation was not feasible.

Period Covered by Runoff Records

In appraising the minimum runoff values obtained by analysis of the 1940-1956 period, against the possibility of lower minimum values occurring in a longer period of record, it is helpful to portray graphically the entire record period of all stream gaging stations in the various watersheds. The series of gage charts referred to as Appendix E show such a graphical portrayal. They show also a physical diagram for each basin, with all the tributaries on which gages are located. The relative location of the gages on these charts corresponds to their geographical proximity in the watershed.

On the bar charts indicating the period of record for each gage, symbols have been placed to show both the calendar year and the water year of minimum runoff during the period of record. These are based, of course, on unadjusted runoff values, but they are of value in comparing recent dry years with those that occurred before 1940 (where records extend back that far).

Determination of Minimum Runoff Values

The date and amount of the minimum annual runoff for each sub-basin are shown in the tabulations of Appendix F as are the date and amount of the minimum monthly runoff with respect to all basins reported on a monthly basis. Note that where negative runoff is shown for a given month - due to absorption of a flood peak, or due to passage of such a peak near the end of a month, so that its full volume is not measured at a downstream station during that month - the minimum monthly runoff during low flow periods also is shown. The minimum values shown cover only the period 1940 - 1956 inclusive, however, the minimum values for most sub-basins will be found in this period, as discussed below.

Minimum daily runoff rates also were determined or estimated for each sub-basin by reference to the records of the U.S.G.S. and the I.B.W.C. These values are listed in Table 5.

Relative Severity of Historic Droughts

The drought of 1950-56 was the most severe of any on record for a large majority of the state's sub-basins, and the minimum annual runoff for most sub-basins clearly occurs during this period. As indicated in the gage charts in Appendix E, there are only a few portions of the Brazos, Colorado and Nueces watersheds where there is definite evidence that the calendar year of minimum runoff occurred prior to 1940. In these instances a comparison of the minimum year with the minimum since 1940 is shown on the charts. Note that in several other instances, shown on the gage charts, the minimum "water year" runoff occurred prior to 1940, but since minimum runoff for this study is reported on a claendar year basis, no account of the earlier minimum "water year" runoffs has been made.

The gage charts indicate how generally the minimum year occurred during the recent drought, and studies by various agencies and consulting engineers confirm that, except in a very few instances, the critical low flow period can be found during the 1940-1956 period.

Significance of Certain Runoff Results

The computation and tabulation of the runoff results by sub-basins throughout the state revealed results which, in some cases, had not been fully anticipated. These merit discussion.

Perhaps the most outstanding unanticipated result was the surprisingly large number and amounts of negative incremental runoff values in sub-basins which receive runoff from basins farther upstream. A good example of this will be noted from examination of the tabulation (Appendix, F-102) for sub-basin 15 B which is the Rio Grande from the El Paso gage down to the Fort Quitman gage, a distance of only 83 river miles. The average annual stream flow at El Paso was 451,777 acre feet for the 1940-1956 period, whereas the average annual streamflow at Fort Quitman was only 320,752 acre feet. The river at that point has actually been dry for many months out of each year at times when there was considerable flow at El Paso. This diminishing flow is, of course, due to the large diversions from the river in the El Paso area, which diversions exceed the "side" inflow to this stretch of the river by an average of 131,025 acre feet per year. This excess of diversions over side inflow is expressed in the tabulations as a negative incremental runoff of the same amount and printed in the computer tabulations as 131,025 acre feet.

The same convention (negative incremental runoff) is followed for reporting all cases where the diversions or other losses from the stream in any sub-basin exceed the side inflow to that sub-basin for any period of time. These negative incremental runoff values may result from several causes, namely:

(1) Consumptive diversions which exceed side inflow to the sub-basin, as in the above example.

(2) Channel losses during low flow which exceed side inflow to the basin.

(3) Passage of a flood peak into a sub-basin near the end of a month so that it does not reach the lower end in time to be recorded that month. In such cases the apparent loss may be compensated by a large runoff the following month.

(4) Actual absorption of flood water in passage through a sub-basin which did not experience the same heavy rainfall which caused the entering flood. This type of loss is shown by the tabulations to be very large in some cases.

(5) Storage of flood inflow in reservoirs (note that the "storage" adjustment made in this report covers only the hypothetical changes in runoff which would result if the reservoirs under construction or completed during the study period had been completed and filled before this period started). Therefore actual storage of floods by reservoirs in normal operation is reflected in the reported runoff values.

(6) Special types of losses, notably on those tributaries of the Nueces River which cross the Balcones Fault and lose a large portion of their flow at this point.

As previously explained, a determination of minimum low-flow monthly runoff values was made and added to the computer output tabulations. No attempt was made, however, to adjust the minimum running totals (at the bottom of these tabulations).

Hence these latter values reflect cases in which large absorptions of flood peaks occurred, and do not necessarily reflect minimum runoff during low flow periods for intermediate sub-basins on many of the watersheds.

Another result that should be noted is that, where a large increase in use had occurred in only one portion of a watershed, application of the use adjustment according to the formula may be inaccurate in a given month because the computed reduction in historic flow for such a month might be larger than the total runoff obtainable at the point of diversion. It does not appear, however, that the aggregate effect of these cases would be important, and since the true picture cannot be obtained without a detailed study, no allowance has been made for this condition, except in sub-basins 10 A and 10 C, where the effect was very pronounced and where a special study was made and the results reported on an annual basis.

Results for the Lower Rio Grande

The results tabulated in Appendix F for the Rio Grande are based on the application of the general formula exactly as in other areas of the state except that in sub-basin 15 I, no storage adjustment was made for Falcon Reservoir. Conditions on the Rio Grande, however, particularly from the Laredo area to the mouth, are quite different from those on other streams. This is due partially to the very large consumptive uses and partially to the effects of applying the U.S.-Mexico Water Treaty provisions to water originating in the United States and Mexico, and to the operation of Falcon Reservoir. Hence the tabulations in Appendix F do not give the true picture of water availability for the sub-basins adjacent to the Mexican border.

The International Boundary and Water Commission has in preparation a report on the proposed Diablo Dam. In this report, the I.B.W.C. has analyzed the effects on water available to the United States in various parts of the watershed based upon:

(1) Historic runoff from 1900 to 1956.

(2) Hypothetical operation of Falcon Reservoir over this period.

(3) Consumptive uses as they now exist and/or can be expected to become in the near future, with full utilization of all existing storage facilities, but without further development.

The results of these studies have been used with the permission of the I.B.W.C. Several of the Commission's tabulations are incorporated in Appendix G, together with the pertinent explanation, and the applicable results are included in the summaries and other results incorporated in this study.

Summary of Runoff by Watersheds

In Appendix H are a series of tabulations, one for each watershed, listing pertinent runoff data for each sub-basin and giving also a diagram of the watershed on which the sub-basins are identified. The values listed in these tabulations are:

(1) Drainage Area in square miles.

(2) Minimum daily runoff in cubic feet per second.

(3) Minimum monthly runoff in acre feet - adjusted for present conditions of use.

(4) Minimum annual runoff in acre feet. Adjusted for

(5) Average annual runoff 1952-1956 in acre feet. present

conditions

(6) Average annual runoff 1940-1956 in acre feet. of use

(7) Cumulative average annual runoff in acre feet. and

storage

Summary of Runoff for State

In addition to the summaries of minimum and average runoff for each watershed of the State in Appendix H the total average runoff is summarized by watersheds in Table 6, which also shows the state total average runoff under present conditions of development and use.

It is not possible to arrive at a total minimum annual runoff by watersheds, because the minimum values often occur in different years, so that a total of them would be meaningless.

Data Shown on Runoff Maps

On Map No. 2 entitled "Runoff From Watersheds and Major Sub-Basins" the essence of the data obtained from this study is shown for each of the sub-basins. On the map itself are shown two figures for each sub-basin, the first giving the minimum annual runoff from that sub-basin and the second giving the average annual runoff for the period 1940-1956 inclusive. In both cases, these are the historic runoff values adjusted for present conditions of use, and for the effects of all storage completed or under construction. The tabulation contained in Table 6 also is shown on this map. Another table shows the minimum daily flows as previously described for all sub-basins in which these flows are determinable and are other than zero.

SUPPLEMENTARY BENEFITS AND USES OF STUDY

Computation of Representative Runoff Rates

Computed on a uniform basis for all areas of the state, the data obtained in this study can be used to obtain representative runoff rates in inches or in acre feet per square mile - for average conditions, minimum month or year, or for any desired period. This information was not included in the study because some selection of data is necessary to give a true picture. In determining runoff rates for sub-basins which receive runoff from an upper sub-basin, for instance, the data must be selected according to whether the sought runoff rates are the incremental rates or the amounts of runoff originating in the sub-basin. Determination of the latter would involve exclusion of certain types of losses previously discussed.

Savings in Time and Effort for Reservoir Yield Studies

Probably the greatest potential use for the results of this study is in making reservoir yield studies, particularly for overall planning or for preliminary studies of specific projects. For overall planning, the runoff results tabulated in Appendix F, or the output data punch-cards which produced these tabulations, could be used directly in many cases for making reservoir yield studies, merely by

Total Texas Runoff 39,711,276* Acre Feet, including only runoff originating in Texas along border streams.

* Including effects of Treaty Provisions.

introducing a factor representing the portion of the sub-basin which is tributary to the reservoirs. In other cases, some further factors would be needed in applying the data, but the compilation of all the data in one volume should save much time and effort in almost any type of yield study.

Use of "Minimum Running Totals" in Preliminary Planning Studies

In all cases where the minimum running totals, tabulated as "Minimum Totals for Periods of Consecutive Months" at the bottom of the computer output data in Appendix F, reflect low flow periods and are not affected by large losses from flood peaks passing through a basin as already discussed, these minimum running totals can be used to select critical periods. They can be used also to obtain preliminary estimates of the yield obtainable from a given amount of storage in a sub-basin, since they will give the minimum inflow to the sub-basin -- or, by proportion, a portion of the sub-basin during the periods of time tabulated. Furthermore, by plotting the tabulated values for any sub-basin and drawing a smooth curve through them, a synthetic mass curve can be plotted from which the minimum inflow can be interpolated for intermediate periods.

Adaptation of Developed Computer Program for Obtaining Additional Data

The program developed can be used directly to obtain similar results from future runoff records on the same sub-basins, and, in some cases, to obtain results for periods prior to 1940. It can also be readily adapted to yield results for portions of any sub-basins, or for different assumptions regarding consumptive uses or operation of existing reservoirs.

It also appears likely that the punch-cards for input and output data can be adapted to produce synthetic runoff data, based on a probability function, for the periods of lowest runoff in any sub-basin which can be expected at any desired frequency, such as once in 100 years.

Establishing of Areas in Which Streamflow Data is Inadequate

In the process of developing the formulas for computing sub-basin runoff, it became very apparent that there is insufficient information to give reliable estimates of runoff in several areas. Detailed examination of the formulas will indicate particular instances where more streamflow measurements would be desirable for certain cases, but in general the following seem to be the most vitally needed points at which additional records are needed.

(1) On the Prairie Dog Town Fork of the Red River at or below the old gage near Estelline.

(2) On the lower Pease River.

(3) On one or more of the Texas creeks tributary to the Red River below the gage at Colbert.

(4) On the Sulphur River below the confluence of the North and South Forks.

(5) At San Jacinto Dam, in the form of a gage which would calibrate spillway overflow and combine this with reported diversions to obtain total runoff at this point.

(6) On several coastal streams where runoff is not materially affected by diversions or return flow, and particularly in watershed 16 J.

(7) On the Clear Fork of the Brazos River near the mouth.

(8) On Pecan Bayou near the mouth.

(9) On the West Fork of the Nueces River above the Balcones Fault.

SUMMARY AND CONCLUSIONS

The complete conclusions resulting from this collection and analysis of data on the runoff from the streams and rivers of Texas under existing conditions of water resources development and use consist of the tabular information contained in the several appendices to this report. The most significant conclusions, in the form of areas, minimum runoff and average runoff from individual sub-basins, together with the total of these values by watersheds, are further shown on the two State maps which accompany this report.

The information contained in the Appendices is summarized in several tabulations in the text of the report, listing, generally by watersheds, the drainage areas, consumptive uses, existing storage in major reservoirs, and minimum and average runoff values.

The conclusions regarding runoff can be summarized further as a single amount of 39,711,276 acre-feet annually, representing the estimated average annual runoff from the entire state, under existing conditions, for the period 1940-1956, inclusive.

The minimum annual runoff cannot be summarized because it occurs at different times for different sub-basins, and therefore a total of these values would be meaningless.

1954	21,973	26,700*	39,000*	104,100			
1954		125,700*				16	854,113
	Sub-basins A, B, E, J, L & M have no storage						
*	Reservoirs considered in storage adjustments						
***	Off Channel Storage						

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #10 Colorado River

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
	A	B	C	E	J	No of Res.	Cumulative Storage Ac-Ft.
1930			12,550			1	12,550
1933				95,000		2	107,550
1938					38,000*	3	145,550
1942					22,000*	4	167,550
1949		29,800*				5	197,350
1952	202,700*	37,200*	80,400*			8	517,650
	Sub-basins D, F, G, H, I, K & L have no storage						
NOTE:	Inks Res., Lake Austin, Granite Shoals*, Marble Falls*, Res.						
	were omitted because use is for power storage with						
	no conservation storage.						
*	Reservoirs considered in storage adjustments.						

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #11 Lavaca River

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
						No of Res.	Cumulative Storage Ac-Ft.
	Sub-basins A & B have no storage						

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #12 Guadalupe River

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
						No of Res.	Cumulative Storage Ac-Ft.
**	366,400*					1	366,400
Subbasins B, C, D, E, & F have no storage							
*	Considered in Storage Adjustments						
**	Under Construction						

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #13 San Antonio River

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
	A					No of Res.	Cumulative Storage Ac-Ft.
1913	249,220					1	249,220

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #14 Nueces River

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
	J					No of Res.	Cumulative Storage Ac-Ft.
1934	39,400**					1	39,400
1957	300,000*					1	300,000
* Considered in Storage Adjustments							
** Flooded out by new Reservoir							

APPENDIX C

CONSERVATION STORAGE IN RESERVOIRS OVER 10,000 AC-FT CAPACITY

W. S. #15 Rio Grande

Year	Subbasins & Conservation Storage in Each - Ac. Ft.					Watershed	
	C	I	J			No of Res.	Cumulative Storage Ac-Ft.
1936	270,000					1	270,000
1940			20,000**			2	290,000
1953		1,222,200*				3	1,512,200
Sub-basins A, B, D, E, F, G & H have no storage							
*	Considered in storage adjustments						
**	Off Channel Storage

ESTIMATED SPECIAL RUNOFF ADJUSTMENTS IN THE RIO GRANDE WATERSHED

PART I. EXCERPTS FROM THE "WATER SUPPLY" SECTION OF THE UNPUBLISHED REPORT OF INTERNATIONAL BOUNDARY AND WATER COMMISSION ON "PROPOSED DIABLO DAM AND RESERVOIR"*

WATER SUPPLY

29. Historical River Flows. Collection of stream-flow records on the Rio Grande below Fort Quitman began in 1900 when 11 stations were established at key points on the river and its tributaries. These were operated until 1914 when, except for a few months in 1919 and 1920, stream gaging on the international portion of the river was suspended until 1923. In that year, gaging resumed with the establishment of 18 stations which have since been operated continuously. Since 1931, when the present joint program of stream gaging by the Commission was adopted, a total of 23 stations have been operated. In order to obtain continuous discharge data since 1900 flows during the 10 missing years, 1914 through 1923, were estimated at the key points from U. S. Weather Bureau gage-height records and other data available during that period.

The 57-year records of historical flows thus obtained at pertinent points, from Fort Quitman to the site of Falcon Dam, are summarized on the following page.

Historical River Flows - Rio Grande 1900-1956, Inclusive
Annual Quantities in Acre-Feet

Location	River Mile	Average	Maximum	Minimum
Fort Quitman	0	335,300	1,550,200	5,900
Lower Presidio (Below Mouth of Rio Conchos)	214	1,380,700	3,526,500	117,700
Langtry (Above Devils and Pecos Rivers)	533	1,874,700	4,279,400	326,100
Diablo Dam Site (Del Rio Station) (Below Devils and Pecos Rivers)	602	2,985,000	6,307,000	727,700
Site of Falcon Dam	893	4,058,600	8,407,100	818,700

30. Source of River Flows. The sources of historic inflows above the Diablo site are tabulated as follows:

---

* Reproduced herein by special permission of the IBWC

Sources of Historical Flows
Passing the Diablo Dam Site 1900-1956
Average Annual Amounts

Source	Acre-Feet	Percent of Total
Rio Grande, Fort Quitman	335,300	11.2
Rio Conchos	1,064,000	35.6
Terlingua Creek)		
Alamito Creek)	54,700	1.8
Pecos River	393,300	13.2
Devils River	515,600*	17.3
Goodenough Spring	97,700	3.3
Unmeasured Sources	524,400	17.6
Total	2,985,000	100

Included in the above total flows are relatively small but important contributions from springs located along the Rio Grande upstream from the Diablo site, a distance of about 300 miles, and along the Devils and Pecos Rivers. The largest, Goodenough Spring, contributes a minimum annual flow of 60,000 acre-feet to the river, and the combined average annual flow of all springs is estimated to amount to about 400,000 acre-feet. The flows are relatively uniform and provide a minimum base flow at the Diablo site of about 500 c.f.s.

The sources of inflows to the river from the Diablo site to Falcon Dam are tabulated as follows:

Sources of Historical Flows
Between Diablo Dam Site and Falcon Dam
Average Annual Amounts

Source	Acre-Feet	Percent of Total
San Felipe and Pinto Creeks	63,600	5.9
San Rodrigo, Escondido,)		
San Diego and Salado Rivers)	670,500	62.5
and Arroyo las Vacas)		
Unmeasured Sources	339,500	31.6
Total	1,073,600	100

Downstream from Falcon Dam to the Gulf, the principal inflows to the river are from the Mexican tributaries Rio San Juan and Rio Alamo, the waters of which are, by the terms of the 1944 Water Treaty, wholly allotted to Mexico. The remaining inflows are from ordinarily dry arroyos which drain the narrow watershed bordering the river below Falcon Dam comprising 2,440 square miles, and are estimated to amount to an average of 226,000 acre-feet annually.

---

* Includes an estimated quantity of 100,000 acre-feet annually contributed below the Devils River gaging station 4.5 miles upstream from mouth, as determined by records secured since August 1954 at mouth of river.

The river flows, largely derived from the highly variable precipitation, vary erratically over wide ranges from year to year and from month to month. Review of the historic flows at Diablo Dam site shows that 50% of the total flow in the 57-year record period occurred in 30% of the years. Characteristic of the historical flows is the occurrence of periods of up to 11 consecutive years of subnormal flows, usually separated by one or two years of much above-normal flows.

31. Channel and Other Losses. The records show that in the section of the river from the Diablo Dam site to Falcon Reservoir, there are during ordinary flows net gains in the river discharge, excluding measured tributary inflows; but at times of floods large net losses occur in the same section. Net losses were especially significant during the 1954 flood when the records show a loss of about 405,000 acre-feet after taking into account seepage returns to the channel which occurred for several months after the flood. Analysis of the records shows that net losses occur in this section whenever river discharges exceed about 50,000 c.f.s. and that the total of the net losses averaged about 30,000 acre-feet annually over the 57-year period of record.

In addition, records of losses from Falcon Reservoir since storage began in August 1953, reflect large losses over and above those due to water-surface evaporation, when the total quantity in storage exceeds about 1,000,000 acre-feet. Such additional losses apparently due to seepage and transpiration amounted to an estimated 300,000 acre-feet during the 1954 flood alone. Study of such losses, assuming Falcon Reservoir had been in operation since 1900 without upstream storage, indicates that they may be expected to average about 145,000 acre-feet annually.

Since about 93% of the flows of the 1954 flood were waters allocated to the United States, of the total of about 705,000 acre-feet of channel and reservoir losses incident to that flood, approximately 650,000 acre-feet of the losses were suffered by the United States. In addition, this country suffered a loss of about 320,000 acre-feet in 1954 by reason of a transfer, under Article 8(b) of the 1944 Water Treaty, of that amount of water to Mexico in Falcon Reservoir, since the United States inflows in that year were more than sufficient to fill its portion of the total conservation storage in Falcon Reservoir. Thus, in 1954 alone, the United States lost nearly 1,000,000 acre-feet of water sorely needed in the years immediately following.

32. Quality of Waters. The records available of chemical analysis of samples of water taken from the Rio Grande below Fort Quitman are summarized in the following table:

Rio Grande Stations	Period of Record	Total Dissolved Solids In Tons Per Acre-Foot		
		Average	Annual Max.	Annual Min.
Fort Quitman	1930 - 1956	2.36	5.25	0.51
La Nutria	1936 - 1941	2.27	2.79	1.96
Upper Presidio	1935 - 1956	1.92	2.74	0.38
Johnson Ranch	1948 - 1956	0.92	1.29	0.84
Langtry	1945 - 1956	0.77	0.83	0.64
Eagle Pass	1935 - 1954	0.95	1.53	0.49
Laredo	July 1955 - 1956	0.71		
Roma	1944 - 1954	0.72	0.95	0.51
Rio Grande City	1934 - 1946	0.88	1.15	0.68
Las Palmas	1946 - 1948	0.69	0.74	0.63
Lower Brownsville	1934 - 1936	0.80	1.03	0.69

According to criteria developed by the U. S. Department of Agriculture, Bulletin No. 962, the results of the sampling indicate that except for the flows in the uppermost reach from Fort Quitman to Upper Presidio, the waters of the Rio Grande may be generally classified as "good".

33. Estimated Future River Flows. In order to develop the quantities of probable future flows of the Rio Grande below Fort Quitman available for regulation and utilization by the two countries, the historical flows for each year were modified by subtracting therefrom the estimated increased depletions which have developed to the present over those which actually obtained in each year beginning in 1900 and were further modified by deducting such additional depletions as are contemplated in the future.

In addition to the historic river and tributary flows, basic data available and used in developing the probable future flows, included information on areas historically irrigated on the United States side contained in the water bulletins of the International Boundary and Water Commission, from an irrigated area survey made in 1932, diversion census in 1938, and irrigated and irrigable area surveys made in 1939 and 1940, all by the United States Section. On the Mexican side, in addition to the irrigated area data contained in the water bulletins, a detailed field investigation was made in 1940 by the Mexican authorities. From these data, estimates were made by each Section of the Commission of areas actually irrigated each year since 1900 in the portions of the basin in its country. To develop the water requirements of the irrigated lands, studies were made by engineers of the two Sections, developing consumptive use coefficients for each portion of the basin using available temperature and precipitation data. In addition, studies were made to develop the effects upon river flows of the reservoirs and regulation works constructed in the basin since 1900, assuming each had been in operation throughout the past 57 years.

Future depletions in the United States portion of the basin were assumed to be those required to serve existing developments. In the Mexican portion of the basin, future depletions included certain increases over those for present developments according to the advice of the Mexican section.

The future flows of the Rio Grande at Fort Quitman were estimated by adjusting the historic flows to indicate the quantities which would have passed that station, if existing works upstream had been in operation since 1900, including: Elephant Butte storage dam (where storage began in 1915), Caballo storage dam (1938), and the irrigation projects downstream therefrom, the American diversion dam and canal (completed in 1938), and the Rio Grande Rectification Project (1938) and Canalization Project (1943). The historic flows at Fort Quitman, estimated to average 335,300 acre-feet per year, were thus reduced to an amount averaging about 191,900 acre-feet per year to reflect probable future flows which will consist principally of irrigation drainage and waste waters.

With respect to tributaries in the United States: on the Pecos River, account was taken that its future flows at the mouth will be limited largely to runoff from the watershed below Red Bluff Dam (completed in 1936) plus return flows from the irrigation project downstream therefrom, with only occasional spills at that dam. The resulting modification of historical flows, which averaged 393,000 acre-feet annually, indicate that future flows of the Pecos River at the mouth will probably amount to an average of about 325,800 acre-feet annually. The historical inflows from Alamito, Terlingua, San Felipe, and Pinto Creeks, which together averaged

118,300 acre-feet, were modified on the basis that the acreage irrigated in the future on these creeks may include the total area under existing works, amounting to 7,700 acres. On this basis, future flows from these named creeks are estimated to average 109,100 acre-feet annually. Neither in the Devils River basin nor near Goodenough Spring is there any irrigation existing or anticipated in the future, and hence the historic flows from these sources which averaged 515,600 and 97,700 acre-feet, respectively, are assumed to obtain in the future.

With respect to tributaries in Mexico: on the Rio Conchos, estimates made by the Mexican Section of future inflows assumed that each of the reservoirs - Boquilla (where storage began in 1914), La Colina (1940), Rosetilla (1940), and Madero (1948), were in operation and that the full contemplated irrigation development in the Rio Conchos basin comprising 286,394 acres was in operation throughout the past 57-year study period. Accordingly, the historical inflows from the Rio Conchos, which averaged 1,064,400 acre-feet per year, were modified such that the average annual future inflows to the Rio Grande are estimated to amount to about 622,500 acre-feet per year. The historical flows of the Arroyo las Vacas, Rio San Diego, Rio San Rodrigo, Rio Escondido, and Rio Salado which together averaged 670,800 acre-feet, were similarly modified to take into account existing and contemplated future depletions, such that the probable future total flow of these tributaries is estimated to average 556,200 acre-feet annually.

From the channel of the Rio Grande, Fort Quitman to Falcon Dam, total future depletions on the United States side were assumed to be those required for irrigation of lands presently under irrigation works which surveys indicate amount to 19,700 acres in the section above the Diablo Dam site, and 66,000 acres in the section downstream therefrom to Falcon Dam. On the Mexican side, future depletions from the main channel were reported by the Mexican Section to be the quantities required for irrigation of about 19,700 acres from Fort Quitman to Diablo Dam site and about 89,500 acres in the section downstream to Falcon Dam. The total quantities of water diverted from the main stream for the contemplated future irrigation of lands on the two banks of the river, estimated from consumptive use studies by the two Sections of the Commission and taking into account the availability of flows in the main stream, amount to an average of about 108,000 acre-feet annually in the section from Fort Quitman to Diablo Dam site, and 413,000 acre-feet annually in the section downstream therefrom to Falcon Dam.

The estimated annual total future flows of the Rio Grande at the Diablo Dam site and at the site of Falcon Dam, as developed from the historical flows on the bases described above, are listed for the 57-year period, 1900 to 1956, in Table 2, appended.

Below Falcon Dam, no depletions are anticipated in the runoff from the portion of the watershed bordering the river (excluding the Rio Alamo and Rio San Juan whose waters are allocated to Mexico), so that the historic inflows from this portion of the watershed estimated to average 226,000 acre-feet annually are expected to obtain in the future.

The resulting estimated average annual depletions and future flows at the key points below Fort Quitman are summarized as follows:

	Total Flows (United States and Mexico) Average Annual Quantities in Acre-Feet		
	Historical Flows	Estimated Average Increased Depletions Over Historical Depletions	Estimated Probable Future Flows
1) At Diablo Dam Site	2,985,000	691,000	2,294,000
2) At Site of Falcon Dam	4,058,600	1,171,600	2,887,000
3) Inflows Below Falcon Dam (excluding Rio Alamo and Rio San Juan)	226,000	0	226,000
Totals 2) + 3)	4,284,600	1,171,600	3,113,000

34. United States Share of Future River Flows. From the estimated total future inflows to the Rio Grande, there were computed the allocations to this country pursuant to the 1944 Water Treaty, which comprise: All of the estimated future waters reaching the main channel from the Pecos and Devils Rivers, Goodenough Spring, Alamito, Terlingua, San Felipe, and Pinto Creeks; one-third of the flow reaching the main channel from the Mexican tributaries, - Conchos, San Diego, San Rodrigo, Escondido, and Salado Rivers and the Arroyo las Vacas, taking into account in accord with the terms of the Treaty that this third shall not be less, as an average annual amount in cycles of five consecutive years, then 350,000 acre-feet, with the proviso that any deficiencies existing at the end of a five-year cycle shall be made up in the following five-year cycle with water from said Mexican tributaries; and one-half of all other flows in the main stream of the river below Fort Quitman not otherwise allotted in the Treaty.

From the allocations thus computed which included allowance for channel losses chargeable to the United States, there were deducted the estimated future uses in this country from the river above Falcon Dam. These, assumed for the purposes of this study to be the quantities of water required to serve domestic uses and lands presently under irrigation works, amount to an average of 54,000 acre-feet annually in the section from Fort Quitman to the Diablo Dam site, and 175,000 acre-feet annually in the section from the Diablo Dam site to Falcon Reservoir, less shortages in this country's share of the supply of natural flows estimated from monthly analysis of available flows and requirements in each section over the 57-year study period, to average 4,000 and 1,000 acre-feet per year, respectively, in the two sections. The resulting estimated uses in the United States amount to an average of 50,000 acre-feet per year in the upper section and 174,000 in the middle section, and total 224,000 acre-feet above Falcon Dam.

The estimated United States share of future flows computed on a monthly basis throughout the 57-year study period at the Diablo site and at the site of Falcon Dam are listed by years in Table 3, appended, and are summarized in average annual amounts in the following tabulation which also shows the estimated United States share of inflows below Falcon Dam:

United States Share of Estimated Future Flows of Rio Grande Below Fort Quitman
Average Annual Amounts in Acre-Feet

	Total Allotted Waters Less U.S. Share of Channel Losses	Estimated Future Upstream Uses	Future Flows	% of Total
1) At Diablo Dam Site	1,536,000	50,000	1,486,000	80
2) At Site of Falcon Dam	1,971,000	224,000	1,747,000	94
3) Inflows Below Falcon	113,000	---	113,000	6
Totals 2) + 3)	2,084,000	224,000	1,860,000	100

35. United States Future Usable Supply With Falcon Reservoir Alone. Under existing conditions of storage on the main stream, the United States future usable water supply from the Rio Grande consists of this country's diversions from the river above Falcon Dam plus its regulated releases at the dam plus the portion of its inflows below the dam which may be diverted as follows:

a. Estimated Future Quantities of Waters Diverted for Use in the United States from its Share of the Natural River Flows Above Falcon Dam, which as described in the previous paragraph, are assumed to amount to an average of 224,000 acre-feet annually.

b. Estimated Future Regulated Releases of United States Waters at Falcon Dam. The probable future flows belonging to the United States at the site of Falcon Dam estimated to amount to an average of 1,747,000 acre-feet, were routed through this country's share of the conservation capacity in the reservoir (1,430,000 acre-feet*), with releases to the extent of the availability of waters in storage** corresponding to present irrigation demands, indicated to average 1,531,000 acre-feet annually. Evaporation from the reservoir water surface and rainfall on the water surface, in excess of that included in the stream-flow records, was estimated from meteorological records in the area to amount to an annual average of 82 inches and 17 inches, respectively. The studies were performed by months throughout the 57-year study period, 1900-1956, beginning with the reservoir empty in 1900, and necessarily also included separate routing of Mexican waters as anticipated by the Mexican Section. The studies were made in accordance with the terms of the 1944 Water Treaty relating to regulation of waters: Evaporation and other losses from the reservoir were divided in proportion to the ownership of waters in storage; and the ownership of inflows belonging to one country whose conservation capacity in Falcon Reservoir was filled and in excess of that needed to keep it filled, passed to the other country, to the extent that that country had unfilled conservation capacity.

---

* During winter months, United States conservation storage capacity in Falcon Reservoir increased to 1,654,000 acre feet.

** Except for 60,000 acre-feet, which it was assumed will be reserved in storage by the State of Texas for domestic use.

The results of the studies indicate that with Falcon Reservoir alone, the United States annual regulated releases therefrom for the downstream will vary from a minimum of about 410,000 acre-feet in a drought year like 1952 to a maximum of 1,878,000 acre-feet and average about 1,348,000 acre-feet.

c. Estimated Future Quantities of Waters Diverted for Use in the United States from its Share of Natural Inflows to the River Below Falcon Dam. Studies made of the records of inflows to the river below Falcon Dam allocated to the United States, estimated to average 113,000 acre-feet annually, indicate that without additional storage and regulation facilities the United States users can divert amounts averaging only about 29,000 acre-feet annually.

To summarize the foregoing: Under future conditions, the total United States usable supply below Fort Quitman with Falcon Reservoir alone is estimated to amount to an average of 1,601,000 acre-feet, comprising:

	United States Usable Supply with Falcon Alone Average Annual Amounts in Acre-Feet
a) Diversions from River Above Falcon Dam.....	224,000
b) Regulated Releases at Falcon Dam.....	1,348,000
c) Diversions from Natural Inflows to River Below Falcon Dam.....	29,000
Total	1,601,000

APPENDIX G

ESTIMATED SPECIAL RUNOFF ADJUSTMENTS IN THE RIO GRANDE WATERSHED

PART II

APPLICATION OF PART I TO STUDY

APPENDIX G PART II

APPLICATION OF PART I TO STUDY

The analysis made by the I.B.W.C. and described in Appendix G, Part I provides a determination of the estimated total flows available to the United States under a combination of Treaty provisions, present conditions of use, including anticipated full use of existing developments, and storage in Falcon reservoir and those completed in Mexico.

The results are shown by the tabulation in paragraph 34 of Appendix G, Part I, and subsequent paragraphs. The amounts of flow so determined as compared to the cumulative total runoff obtained from the analysis in this study are as follows:

ALL QUANTITIES IN ACRE FT./YR.

	ESTIMATED BY IBWC				
	Total Available to U.S.	Diversions not incl. in flow measurement	Remainder	Results of this study	Additional Water not incl. in study Avail. to U.S.
At Diablo Dam Site (Subbasin 15G)	1,536,000	50,000	1,486,000	1,142,378	343,622
Inflow, Diablo D.S. to Chapeno Gage 15H & 15I Falcon Dam Site Subbasin 15I	435,000	124,000	261,000	37,843	223,157
Sub-total	1,971,000	224,000	1,747,000	1,180,221	566,779
Inflow Sub-basin 15J	113,000	1,560,000	-1,447,000	-1,323,299	-123,701
Total Mouth of River	2,084,000	1,784,000	300,000*	-143,078 (Deficiency)	443,078

The amounts shown in the right-hand column of the above tabulation may be taken to represent the additional water available to the United States which is not included in the runoff results obtained by this study.

These additions are included as separate items on the summary in Table 6 and are indicated by notes on Map No. 2.

* Deficiency exists in years when flow is below average.

APPENDIX H

SUMMARY OF RUNOFF

BY WATERSHEDS

SUMMARY OF RUNOFF AND RUNOFF RATES FOR WATERSHED NO. 1 CANADIAN RIVER

As developed in Appendix G, it is estimated under present conditions that the Cumulative Average Flows available to the U.S. after diversion are as follows:

At Subbasin 15G 1,486,000 Ac.Ft/Yr.
At Subbasin 15I 1,747,000 Ac.Ft/Yr.
At Subbasin 15J 300,000 Ac.Ft/Yr.
