September 1946

Viente de ellas

The present public water supply of the City of Amarillo, all of which is obtained from wells, is not adequate to take care of the needs of the city during periods of peak demand. To meet this situation and to provide for still greater needs in the future the city is planning to explore new territory for an additional supply of ground water. In this connection the Texas State Board of Water Engineers and the Geological Survey, U. S. Department of the Interior, have been requested by the city authorities to investigate the ground-water resources in an area of several hundred square miles in northwestern Randall County and adjacent territory in Potter, Oldham, and Deaf Smith Counties (see map).

This report is based in part on studies made in the spring and summer of 1946, in response to the city's request, and in part on data collected by the Board of Water Engineers and the Geological Survey in 1937 and 1942. It contains records of 239 wells, of which 27 are used by the city of Amarillo, 72 for irrigation, 3 for industrial purposes, 83 principally for domestic purposes and stock, 28 are not used, and 26 were drilled as test wells. It also includes drillers' logs of 45 wells, chemical analyses of water from 45 wells, measured or estimated yields of the more productive wells, records of pumpage by the city of Amarillo from 1928 to 1944, and depth to water in most of the wells.

SOURCE OF GROUND WATER

Thickness and character of Ogallala deposits

The area covered by this report lies on the High Plains of Texas near the northern extremity of the South Plains or Llano Estacado. Most of the usable ground water in the area occurs in sands and gravels of the Ogallala formation which appears at or near the surface and lies on an uneven floor of Triassic "red beds". The "red beds" are exposed to the north and northwest of the area in the breaks of the Canadian River, and to the southeast of it in Palo Duro Canyon.

The Ogallala deposits consist principally of eroded material from high areas to the west and northwest brought in and deposited by streams. They consist of sand, silt, gravel, and clay, which in some places are comented by calcareous material. In common with most stream deposits, the thickness and gradation of the water-bearing sands and gravels in the Ogallala varies widely from place to place. In some places the saturated portion of the formation consists chiefly of good water-bearing sand and gravel but in other places it consists dominantly of fine sands, silts or clays. Because of these irregularities, the best location for production wells can be determined only by test drilling.

Twenty-four of the wells listed in the tables are reported to have been drilled through the Ogallala formation to the Triassic "red beds", and to have penetrated from 220 to 310 feet of Ogallala deposits. Based on these figures and water level measurements made in part before heavy pumping was started, the thickness of the zone of saturation in the Ogallala beds in 19 of the wells was estimated to range from 67 to 166 feet.

Pumpage

City of Amarillo - The first large-scale pumping in the area took place when Amarillo developed its Palo Duro well field about 16 miles southwest of the city. This development consists of a reservoir and 10 wells (nos. 51 to 60), and a 30-inch pipe line for conveying water to the city (see map). The reservoir is formed by a dam about 40 feet in height on Palo Duro Creek and is said to have a capacity of about 5,000 acre-feet, or about 1,630,000,000 gallons. The reservoir, wells, and pipe line were completed in 1927, but the reservoir did not fill until 1931, and it is said to have reached a level above the spillway only twice. No water is diverted from the reservoir, its function being to replenish the sands and gravels from which the adjoining wells are supplied. The wells are near the reservoir, part of them being immediately below the dam and the others along the shores of the reservoir not far upstream from the dam. The most distant well is about one-fourth mile from the north shore. According to records of several pumping tests made in the first seven months of operation, the wells had a yield ranging from 460 to about 700 gallons a minute each.

In 1931 five wells (nos. 71 to 75) were drilled about 5 miles southwest of the city in what is now known as the McDonald well field. Four of these wells are located along the pipe line at intervals of about 2,000 feet. The fifth well is about 2,000 feet west of the pipe line. According to tests made by the city, the yield of these wells is about 750 gallons a minute each.

Between 1943 and 1945, 12 new wells were drilled along the pipe line, one (no. 77) between the McDonald well field and the city and the others (nos. 61 to 70 and 76) between the McDonald and Palo Duro well fields. According to tests made by the city, these wells yield from 700 to 1,340 gallons a minute each and five of them yield more than 1,000 gallons a minute each.

The pumpage from the Palo Duro and McDonald well fields from 1928-29 to 1943-44 is given in the following table:

	(From ci	ty records for :	fiscal years 19	28 through	1944)

Pumpage by the City of Amarillo, Texas (From city records for fiscal years 1928 through 1944

As shown by the table pumpage by the city increased from 1,005,910,000 gallons a year in 1928-1929 to 2,602,800,000 gallons a year in 1943-1944, or from an average of 2,700,000 a day to an average of 7,100,000 gallons a day. Records of the city pumpage from April 1944 to date are not at hand. In the summer of 1946 the peak demand is said to have been more than 19,000,000 gallons a day.

Irrigation - Irrigation from wells in the area is said to have been started about 13 years ago by W. D. Muncoy, a local well driller. In 1940 the irrigation wells in the area numbered 24 and in the spring of 1946 the number had reached 72. In the spring of 1946 the pump discharge from 13 of these wells was measured and found to range from 150 to 1,140 gallons a minute. No accurate information is at hand as to the total number of acres irrigated nor as to the total amount of water pumped for irrigation. In the South Flains as a whole it is estimated that the pumpage averages about 100 acre-feet per well. On this basis the total pumpage from the 72 irrigation wells in the area would amount to 7,200 acre-feet or an average of about 6,500,000 gallons a day throughout the year.

Fluctuation of water levels in wells

For several years measurements of water levels in three wells, nos. 83a, 124, and 149, in the eastern part of the area, have been made periodically by the Texas State Board of Water Engineers and the Geological Survey. Wells 83a and 124, comparatively remote from heavy pumping, show practically no decline in water levels since 1938, Well 149, however, near an area of heavy irrigation pumping and only about $l\frac{1}{2}$ miles from the center of the McDonald field, shows a net decline of 3.7 feet between the spring measurements in 1938 and 1946, of which 2.3 feet occurred between 1943 and 1946, Measurements made by the City indicate that a considerable decline in water levels has occurred in

N 84.

some of the City wells. These measurements, however, were made under varying conditions of pumping and shutdown, both in the well itself and in neighboring wells, and cannot be accurately evaluated.

Quality of water

The analyses of water from 45 wells drawing water from the Ogallala are given in the tables of analyses of water in this report. The results of the analyses show a fair degree of uniformity in the chemical character of the water throughout the area. The total dissolved solids in the 45 samples ranged from 200 to 437 parts per million. The water is all of good quality except that the total hardness (averaging about 250 parts per million) and the fluorides (3 analyses averaging 3.2 parts per million) are high.

Summary

This report consists primarily of records of wells, and pumpage from wells, in an area of several hundred square miles on the Texas High Plains, south, southwest and west of Amarillo. The withdrawals of ground water from this area for the public supply of Amarillo increased from an average of 2,700,000 gallons a day in 1928-29 to an average of 7,100,000 gallons a day in 1943-44, and they are believed to have been still greater in 1944-45 and 1945-46. From 1940 to 1946 the number of irrigation wells in the area increased from 24 to 72 and it is estimated that the total pumpage for irrigation now amounts to about 7,200 acrefeet a year, which is the equivalent of an average of about 6,500,000 gallons a day throughout the year. Most of the pumping for both public supply and irrigation is in the eastern part of the area. In the central and western parts ground-water development is limited to a few scattered irrigation and ranch wells.

In the eastern part of the area two observation wells that are comparatively remote from heavy pumping show practically no decline in water levels from 1938 to 1946, and one well near heavy pumping shows a net decline of 3.7 feet during the same period, of which 2.3 feet occurred between 1943 and 1946. Measurements made by the city indicate that a considerable decline of water levels has occurred in some of the city wells but these records cannot be accurately evaluated because they were made under varying conditions of pumping and shut down.

It is understood that if additional development is made by the City in this general direction the practically unexplored territory to the west of the area of heavy pumping probably will be selected. Comparatively little is known regarding ground-water conditions in that territory. The data that are available indicate that a large supply of ground water may be available, but the Ogallala formation practically everywhere varies materially in character and thickness. In some places the saturated portion of the formation may consist chiefly of good water-bearing sand and gravel while in others fine sands, silts, or clays may predominate. Because of these probable irregularities test drilling and pumping are needed in order to determine the best location for production wells. - 5 -
